Common genetic contributions to mental illness discovered 18, 2011 in two papers in the journal Nature Genetics. represent significant
Researchers have long known that genes influence mental illness. Five years ago, for example, the global Psychiatric Genomics Consortium found that people with autism, schizophrenia, bipolar disorder, depression, and attention-deficit hyperactivity disorder frequently share certain DNA variations. But that 2013 study did not say how those genetic alterations might lead to symptoms. In another surprise, Geschwind, Gandal, and their colleagues found essentially zero correlation in gene activity patterns between alcoholism and the other four disorders. Many studies in identical twins, who have largely identical DNA, had suggested that the genetic risk factors for major depression and alcohol use disorder are similar, Kendler says. Mental illnesses are characterized by disorders of the psyche, or mind. The view of objective reality is impaired, as are also the patient's self-correctness, his attitudes towards others and his behaviour. Some mental diseases are the result of primary affection of the brain, followed by a disturbance of the body as a whole. Others are caused by diseases of particular organs, with secondary disturbance of mental functions. They may be manifested in a variety of disorders: false sensory impressions, disturbances in thinking or mood, disturbances of consciousness and memory, and intellect
